

SwingScope

User Guide

How to go from opening the app to placing a trade, in eight steps.
Written for someone who knows how to buy a stock but has never
used a systematic screener.

Research tool. Not investment advice.
30-day holding period · NSE equities · 29 July 2026

Before anything else

One thing to understand before you use this app for money

There is no live evidence yet.

Every number in the app comes from historical testing on data the signal was also selected from. That testing has already been wrong once: a five-year test showed a 1.42% edge, and a twenty-year test showed 0.46% — the first result did not generalise.

The forward log is the check that cannot be gamed, and it needs eight weeks. Until then, paper trade. If you trade sooner, size it as tuition rather than investment.

Why 30 days and not 15

You may have expected a 15-day swing horizon. Testing showed 15 days does not work once costs are counted:

Holding period	Long-only edge	After costs and 20% tax	
15 days	0.77%	-1.15% annualised	loses money
30 days	2.16%	+5.95% annualised	viable
60 days	2.79%	+4.44% annualised	viable

Charges are roughly 0.36% per round trip and short-term capital gains tax is 20%. A 15-day cycle pays those too often for the edge to survive. **Thirty days is not swing trading in the usual sense** — it is closer to position trading, with different drawdowns and a different demand on your patience.

The weekly process

About fifteen minutes, once a week

SwingScope — Weekly User Process

About 15 minutes, once a week

STOP — before any of this

Zero forward evidence exists yet. Paper trade for 8 weeks first.
If you trade sooner, size it as tuition.

Step 1 — Read the regime banner

This is the first thing on the Screener tab and it governs everything below it. Read it before you look at a single stock.

Step 1 — What the Regime Banner Tells You

Risk-off does not mean the market will fall. It means the conditions your signal was validated in are absent. Momentum works by trends persisting; below the 200-day average trends reverse more often, and that is precisely when momentum strategies suffer their worst losses.

The regime is recomputed on every run. Nothing is manual — it flips by itself the moment the index closes back above its 200-day average.

Step 2 — Check selectivity

In the metrics row you will see **Selectivity: top X%**. This is the single most misread number in the app.

Reading	What it means	Action
top 4%	Matches the validated setup	proceed
top 7%	Close enough	proceed
top 17%	App warns you	widen the universe

top 34%	Not the validated setup at all	probably skip the week
---------	--------------------------------	------------------------

The edge lives in concentration. Testing showed a 1.63% gross spread taking the top 5% of a ranked set, against 0.56% for the top 20%. If filters have cut 400 candidates to 29 before selection, taking 10 of those is the top 34% — a much weaker filter than the one that was tested.

Step 3 — Build the bucket

The table showing stocks that passed filters is a *candidate list*, not your picks. Click **Build today's bucket**.

The bucket applies what the table does not: the regime cap on how many positions are permitted, sector limits, tier balance, and volatility scaling. From 29 candidates in a risk-off regime you would typically get three.

Step 4 — Read the popup

- **Regime and count** — how many picks, and why that number
- **Tier mix** — large / mid / small breakdown
- **How this bucket was built** — every exclusion, with its reason
- **Plain text** — formatted for pasting into Telegram or a notebook

Step 5 — Size each position

Step 5 — How a Position is Sized

Worked example: BHARATFORG at ₹2,181 with ₹5,00,000 capital

Capital	₹5,00,000	<i>your account</i>
Risk per trade	1% = ₹5,000	<i>the most you lose if the stop hits</i>
ATR (14-day)	2.4% = ₹52	<i>typical daily range</i>
Stop multiple	2.0 × ATR	<i>tier-specific, large cap</i>
Stop distance	₹105 (4.8%)	$2.0 \times ₹52$
Stop price	₹2,076	$₹2,181 - ₹105$
Quantity	$₹5,000 \div ₹105 = 47$	<i>risk ÷ stop distance</i>
Position value	₹1,02,507	$47 \times ₹2,181$
% of capital	20.5%	<i>within the 25% large-cap cap</i>

The quantity is arithmetic, not conviction.
A more volatile stock gets a WIDER stop and therefore a SMALLER position —
so every trade risks the same rupee amount regardless of the stock.

Open the Detail tab for each pick. The app computes the stop and quantity for you. **Do not override the quantity upward.** It is arithmetic derived from your risk limit and the stock's volatility, not an opinion about the stock.

Step 6 — Check total exposure

Individual position caps do not bound the total. Ten positions each within their own limit can sum to twice your capital, because a tight stop implies a large position. Sum the values before you place anything.

- **Gross exposure under 100%** — above that is leverage you did not choose
- **Total risk under 6%** — this assumes every stop hits at once, which is exactly what a gap-down does
- **Effective bets 3 or more** — ten correlated names are one position wearing ten labels

Step 7 — Place the orders yourself

The app never trades. It cannot place, modify or cancel an order, and that is deliberate — the judgement between a ranked list and an actual purchase is doing real work.

Prices are end-of-day and delayed. **Confirm every level on your broker terminal** before acting on it.

Step 8 — Record it

Use the Journal tab, or let the Monday automation record the bucket for you. Either way the position needs to exist somewhere you will look at in eight weeks.

The checklist

The Go / No-Go Checklist

Any single NO means do not take that trade

☐	Regime is not RISK OFF <i>If red: 3 large caps maximum, and often zero is right</i>
☐	Selectivity is top 15 percent or better <i>Above that it is not the validated setup</i>
☐	Pick survives the earnings check <i>Results inside 30 days is a coin flip</i>
☐	Total exposure under 100 percent <i>Above means leverage you did not choose</i>
☐	Total risk under 6 percent of capital <i>Assumes every stop hits at once — a gap does that</i>
☐	Effective bets is 3 or more <i>Below that, ten names behave as one position</i>
☐	Stop sits inside the daily price band <i>Non-F&O stocks can lock limit-down</i>
☐	You can genuinely hold for 30 days <i>15 days does not clear costs after tax</i>

If several say NO, that is not a broken app.

It is telling you conditions do not support the strategy today.

What to expect

Most weeks you will not trade

In a risk-off regime the bucket caps at three, and often the honest answer is zero. That is the design working. The most common error with a system like this is trading because a week felt quiet.

Any single trade is close to a coin flip

The top decile of momentum stocks rose 54.7% of the time. The universe average was 54.9%. Top and bottom decile outcome distributions **overlap 87%**.

The edge is in average magnitude across many trades, not in being right more often. That has a practical consequence: **do not develop conviction about individual picks**. The model has none.

The range of outcomes is wide

For a stock scoring 95, the middle 80% of historical outcomes ran from -13.8% to +23.8% over 30 days. The median was +1.86%.

Where to look things up. The Outcomes tab shows the full historical distribution for any score. The Method tab documents how the signal was built and what failed along the way. Both are worth an unhurried read once.

If you are managing money for others

This is a research tool, not an advisory product. Presenting its output as investment advice to clients may require registration with SEBI as a Research Analyst or Investment Adviser. Take proper legal advice before doing so.

Educational and research use only. Not investment advice. Prices are end-of-day and delayed. A high score reflects chart properties, not a prediction. Swing trading carries real risk of capital loss, and SEBI studies find most active retail traders lose money net of costs. Consider consulting a SEBI-registered adviser.
